(54) **Non-aqueous electrolyte and electrochemical device comprising the same**

(57) A non-aqueous electrolyte is disclosed, which comprises a non-aqueous solvent and a solute represented by the general formula(1): $MBR^1R^2R^3R^4$, where in M is an alkali metal atom or an ammonium group and R^1 to R^4 are each independently electron withdrawing groups or electron withdrawing atoms bound to B where at least one of R^1 to R^4 is other than a fluorine atom. The solute has a thermal stability substantially equal to

that of $LiBF_4$ and an anion portion having a high electronegativity, and easily dissociates into ions. Therefore, a non-aqueous electrolyte containing this solute has a high ionic conductivity and is difficult to cause a generation of a gas or deterioration in characteristics due to the decomposition of the solute, which occurs during use at high temperatures or after storage at high temperatures.

Description

BACKGROUND OF THE INVENTION

[0001] Electrochemical devices comprising a non-aqueous electrolyte have been used in a wide range of electric and electronic appliances. Such electrochemical devices include, for example, non-aqueous electrolyte batteries such as a lithium battery, and capacitors such as an electric double layer capacitor and an electrolytic capacitor.

[0002] It is desirable that a non-aqueous electrolyte comprising a non-aqueous solvent and a solute has a high ionic conductivity. In order to obtain such a non-aqueous electrolyte, a non-aqueous solvent having a high dielectric constant and a low viscosity is required. However, a non-aqueous solvent having a high dielectric constant usually has a strong polarity and therefore has a high viscosity. Thus, a mixed non-aqueous electrolyte containing a non-aqueous solvent with a high dielectric constant such as ethylene carbonate (dielectric constant: 90) and a non-aqueous solvent with a low dielectric constant such as dimethyl carbonate (dielectric constant: 3.1) or ethyl methyl carbonate (dielectric constant: 2.9) is commonly used.

[0003] As the solute constituting the non-aqueous electrolyte, for example, LiPF_6 , LiClO_4 , LiBF_4 , LiAlCl_4 , LiSbF_6 , LiSCN , LiCl , LiAsF_6 , LiCF_3SO_3 , $(\text{CF}_3\text{SO}_2)_2\text{NLi}$ or the like is used. Among them, LiPF_6 is most frequently used because it has a wide potential window and thus provides a non-aqueous electrolyte having a high ionic conductivity.

[0004] While a non-aqueous electrolyte containing LiPF_6 has a high ionic conductivity of approximately 8.5 mS/cm at room temperature, it has a low thermal stability. Moreover, LiPF_6 is problematic in that it reacts sharply with moisture to decompose. HF , PF_5 or the like produced by the decomposition of LiPF_6 has an adverse effect on an electrochemical device. Accordingly, when an electrochemical device, which comprises a non-aqueous electrolyte containing LiPF_6 , is used for an appliance generating a great amount of heat, the performance of the electrochemical device may deteriorate or a gas may be generated inside the device.

[0005] Although the uses of LiSO_2CF_3 , $(\text{CF}_3\text{SO}_2)_2\text{NLi}$ and the like have also been investigated, they are not proceeding towards practical utilization. This is because many of solutes containing an organic anion tend to cause a corrosion of a current collector made of aluminum, which is used in the positive electrode of a non-aqueous electrolyte battery.

[0006] On the other hand, LiBF_4 , which is commonly used in lithium primary batteries, has a higher thermal stability as compared with LiPF_6 and a potential window substantially equal to that of LiPF_6 . However, a non-aqueous electrolyte obtained by dissolving LiBF_4 in a non-aqueous solvent has a low ionic conductivity of about 2.9 mS/cm at room temperature. For this reason, LiBF_4 is not used in lithium secondary batteries.

[0007] The reason why LiBF_4 has a lower ionic conductivity as compared with LiPF_6 is that only four fluorine atoms having an electron withdrawing property are bound to one boron atom in LiBF_4 , whereas six fluorine atoms are bound to one phosphorus atom in LiPF_6 . Since electronegativity depends on the number of the bound fluorine atoms, the electronegativity of the BF_4 anion is lower than that of the PF_6 anion. Therefore, it is considered that LiBF_4 is difficult to dissociate into a Li cation and a BF_4 anion. Moreover, because the BF_4 anion has a small ionic diameter, it tends to cause an association thereby to deteriorate the ionic conductivity of the electrolyte.

[0008] The dielectric loss in an electrolytic capacitor is greatly affected by the ionic conductivity of the non-aqueous electrolyte interposed between a negative electrode foil and a dielectric layer which comprises an oxide of aluminum or tantalum disposed on a positive electrode foil. When the dielectric loss is great, the frequency characteristics and the charge/discharge characteristics of the electrolytic capacitor are deteriorated. Nevertheless, a non-aqueous electrolyte accommodated in an electrolytic capacitor contains a solute which dissociates to produce a BF_4 anion, resulting in a great dielectric loss in the capacitor.

BRIEF SUMMARY OF THE INVENTION

[0009] In view of the above situation, it is an object of the present invention to provide a non-aqueous electrolyte having a high thermal stability as well as a high ionic conductivity.

[0010] More specifically, the present invention relates to a non-aqueous electrolyte comprising a non-aqueous solvent and a solute represented by the general formula (1): $\text{MBR}^1\text{R}^2\text{R}^3\text{R}^4$, wherein M is an alkali metal atom or an ammonium group and R^1 to R^4 are each independently electron withdrawing groups or electron withdrawing atoms bound to B where at least one of R^1 to R^4 is other than a fluorine atom.

[0011] In the general formula (1), it is preferred that at least one of R^1 to R^4 is represented by the general formula (2): $\text{C}_m\text{F}_{2m+1}\text{SO}_2$, where n is an integer of 1 to 4; or the general formula (3): $\text{C}_m\text{F}_{2m+1}\text{SO}_2$, where m is an integer of 1 to 4. Further, the reminders of R^1 to R^4 are preferably fluorine atoms.

[0012] For the solute represented by the general formula (1), it is preferred to use at least one selected from the group consisting of $\text{LiB}(\text{CF}_3)_4$, $\text{LiB}(\text{CF}_3)_3$, $\text{LiBF}_2(\text{CF}_3)_2$, $\text{LiBF}_3(\text{CF}_3)$, $\text{LiB}(\text{C}_2\text{F}_5)_4$, $\text{LiBF}(\text{C}_2\text{F}_5)_3$, $\text{LiBF}_2(\text{C}_2\text{F}_5)_2$, $\text{LiBF}_3(\text{C}_2\text{F}_5)$, $\text{LiB}(\text{CF}_3\text{SO}_2)_4$, $\text{LiBF}(\text{CF}_3\text{SO}_2)_3$, $\text{LiBF}_2(\text{CF}_3\text{SO}_2)_2$, $\text{LiBF}_3(\text{CF}_3\text{SO}_2)$, $\text{LiB}(\text{C}_2\text{F}_5\text{SO}_2)_4$, $\text{LiBF}(\text{C}_2\text{F}_5\text{SO}_2)_3$, LiBF_2

[0020] While the novel features of the invention are set forth particularly in the appended claims the invention, both as to organization and content, will be better understood and appreciated, along with other objects and features thereof, from the following detailed description taken in conjunction with the drawings.

BRIEF DESCRIPTION OF THE SEVERAL VIEWS OF THE DRAWING

[0021] FIG. 1 is a vertical sectional view showing a cylindrical non-aqueous electrolyte battery of the present invention.

[0022] FIG. 2 is a diagram showing a circuit of a device used for evaluating the frequency characteristics of an electrolytic capacitor.

[0023] FIG. 3 is a graph showing the change in the potential difference between the both electrode foils of an electrolytic capacitor of the present invention on which a pulse voltage is applied.

DETAILED DESCRIPTION OF THE INVENTION

[0024] The present invention uses a solute which has a thermal stability substantially equal to that of LiBF_4 and has an anion portion having a high electronegativity, and easily dissociates into ions in a non-aqueous solvent. Examples of the solute include ones having one or more perfluoroalkyl group represented by the general formula: $\text{C}_n\text{F}_{2n+1}$ or perfluoroalkylsulfonic acid group represented by the general formula: $\text{C}_m\text{F}_{2m+1}\text{SO}_2$ bound to the boron atom. Since a perfluoroalkyl group and a perfluoroalkylsulfonic acid group have a strong electron withdrawing property, a solute having either of these groups easily dissociates into ions in a non-aqueous solvent. Accordingly, the use of the above solutes can provide a non-aqueous electrolyte having a high thermal stability as well as a high ionic conductivity and, furthermore, it can provide a non-aqueous electrochemical device capable of conducting an efficient high-rate charging and discharging.

[0025] It is considered that the more the number of the electron withdrawing groups bound to a boron atom of a solute is, the greater the electronegativity of the anion portion of the solute and the tendency thereof to dissociate into ions become. It is also considered that the more the number of the electron withdrawing groups bound to a boron atom of a solute is, the greater the anionic diameter of the solute becomes and the smaller the tendency thereof to cause an association becomes.

Embodiment 1

[0026] In this embodiment, descriptions will be made on a preferred non-aqueous electrolyte for use in a lithium primary battery, a lithium secondary battery, a lithium ion battery, a polymer battery and the like. A non-aqueous electrolyte of this embodiment can be obtained by dissolving the following solute in the following non-aqueous solvent.

(j) Solute

[0027] A non-aqueous electrolyte of this embodiment contains a solute represented by the general formula: $\text{M}^+\text{B}^-\text{R}^1\text{R}^2\text{R}^3\text{R}^4$, wherein M^+ is an alkali metal atom such as Li, Na or K and R^1 to R^4 are electron withdrawing groups or electron withdrawing atoms bound to a boron atom where at least one of R^1 to R^4 is other than a fluorine atom.

[0028] It is preferred that at least one of R^1 to R^4 is a group represented by the general formula: $\text{C}_n\text{F}_{2n+1}$, where n is an integer of 1 to 4, or a group represented by the general formula: $\text{C}_m\text{F}_{2m+1}\text{SO}_2$, where m is an integer of 1 to 4. The remainders are preferably fluorine atoms.

[0029] Since an anion having a group represented by the general formula: $\text{C}_n\text{F}_{2n+1}$ is smaller than an anion having a group represented by the general formula: $\text{C}_m\text{F}_{2m+1}\text{SO}_2$, a non-aqueous electrolyte containing the former anion has a higher ionic conductivity than the latter one. Therefore, the group represented by the general formula: $\text{C}_n\text{F}_{2n+1}$, where n is an integer of 1 to 4 is more preferred than the group represented by the general formula: $\text{C}_m\text{F}_{2m+1}\text{SO}_2$, where m is an integer of 1 to 4.

[0030] The number of the electron withdrawing group other than a fluorine atom may be one or more; however, it is more preferably 2 to 3 from the viewpoint of, for example, ease of the synthesis of the solute. Preferred examples of the solute include solutes represented by the general formula: $\text{M}^+\text{B}^-(\text{C}_n\text{F}_{2n+1})_2\text{F}_2$ or solutes represented by the general formula: $\text{M}^+\text{B}^-(\text{C}_n\text{F}_{2n+1})_3\text{F}$.

[0031] Although n and m may be an integer of 1 to 4, it is more preferred that they are 2. The reason is that the electron withdrawing effect of the electron withdrawing group decreases when n and m are too small, and the anionic diameter increases when n and m are too large.

[0032] Specific examples of the solute include $\text{LiB}(\text{CF}_3)_4$, $\text{LiBF}(\text{CF}_3)_3$, $\text{LiBF}_2(\text{CF}_3)_2$, $\text{LiBF}_3(\text{CF}_3)$, $\text{LiB}(\text{C}_2\text{F}_5)_4$, $\text{LiBF}(\text{C}_2\text{F}_5)_3$, $\text{LiBF}_2(\text{C}_2\text{F}_5)_2$, $\text{LiBF}_3(\text{C}_2\text{F}_5)$, $\text{LiB}(\text{CF}_3\text{SO}_2)_4$, $\text{LiBF}(\text{CF}_3\text{SO}_2)_3$, $\text{LiBF}_2(\text{CF}_3\text{SO}_2)_2$, $\text{LiBF}_3(\text{CF}_3\text{SO}_2)$, $\text{LiB}(\text{C}_2\text{F}_5\text{SO}_2)_4$, $\text{LiBF}(\text{C}_2\text{F}_5\text{SO}_2)_3$, $\text{LiBF}_2(\text{C}_2\text{F}_5\text{SO}_2)_2$, $\text{LiBF}_3(\text{C}_2\text{F}_5\text{SO}_2)$ and the like. They may be used singly or as a mixture of two or more of them.

[0033] The non-aqueous electrolyte may further contain LiClO_4 , LiBF_4 , LiPF_6 , LiAlCl_4 , LiSbF_6 , LiSCN , LiCF_3SO_3 , LiCF_3CO_2 , $\text{Li}(\text{CF}_3\text{SO}_2)_2$, LiAsF_6 , $\text{LiB}_{10}\text{Cl}_{10}$, a lithium lower aliphatic carboxylate, LiCl , LiBr , LiI , chloroborane lithium,

borates such as bis(1,2-benzenediolate(2-)-O,O') lithium borate, bis(2,3-naphthalenediolate(2-)-O,O') lithium borate, bis(2,2'-biphenyldiolate(2-)-O,O') lithium borate and bis(5-fluoro-2-olate-1-benzenesulfonic acid-O,O') lithium borate, imide salts such as bistetrafluoromethanesulfonic acid imide lithium ($(CF_3SO_2)_2NLI$), tetrafluoromethanesulfonic acid nonafluorobutanesulfonic acid imide lithium ($LIN(CF_3SO_2)(C_4F_9SO_2)$) and bis(pentafluoroethanesulfonic acid imide lithium ($(C_2F_5SO_2)_2NLI$)).

(ii) Non-aqueous solvent

[0034] Examples of the non-aqueous solvent include: cyclic carbonic acid esters such as ethylene carbonate, propylene carbonate, butylene carbonate and vinylene carbonate and derivatives thereof; non-cyclic carbonic acid esters such as dimethyl carbonate, diethyl carbonate and ethyl methyl carbonate and derivatives thereof; cyclic carboxylic acid esters such as γ -butyrolactone and γ -valerolactone and derivatives thereof; aliphatic carboxylic acid esters such as methyl formate, methyl acetate, methyl propionate and ethyl propionate and derivatives thereof; non-cyclic ethers such as dimethoxyethane, diethyl ether, 1,2-dimethoxyethane, 1,2-diethoxyethane, ethoxymethoxyethane and 1,3-dimethoxypropane and derivatives thereof; cyclic ethers such as tetrahydrofuran, 2-methyltetrahydrofuran and 1,3-dioxolane and derivatives thereof; other solvents such as dimethylsulfoxide, formamide, acetamide, dimethylformamide, dioxolane, acetonitrile, propylnitrile, nitromethane, ethyl monoglyme, phosphoric acid triesters, trimethoxymethane, dioxolane derivatives, sulfolane, methylsulfolane, 1,3-dimethyl-2-imidazolidinone, 3-methyl-2-oxazolidinone, ethyl ether, 1,3-propanesultone, anisole and N-methylpyrrolidone; and the like. They may be used singly or as a mixture of two or more of them.

[0035] Although the concentration of the solute in the non-aqueous electrolyte is not particularly limited, it is preferably 0.2 to 2 mol/liter, and more preferably 0.5 to 1.5 mol/liter.

Embodiment 2

[0036] In this embodiment, descriptions will be made on a non-aqueous electrolyte battery comprising the non-aqueous electrolyte of Embodiment 1. This battery comprises a positive electrode; a negative electrode; a separator interposed between the positive electrode and the negative electrode; and the above non-aqueous electrolyte.

(i) Negative electrode

[0037] The negative electrode is fabricated, for example, by applying onto the surface of a current collector, a negative electrode mixture containing a negative electrode active material, a conductive agent, a binder and the like.

[0038] As the negative electrode active material, for example, lithium metal or a material capable of absorbing and desorbing lithium is used.

[0039] Examples of the material capable of absorbing and desorbing lithium include: thermally decomposed carbon; cokes such as pitch coke, needle coke and petroleum coke; graphites; glassy carbons; phenol resins, materials obtained by sintering and carbonizing furan resins or the like at an appropriate temperature; carbon materials such as carbon fibers and activated carbons; polymer materials such as polyacetylene, polypyrrole and polyacene; lithium-containing transition metal oxides such as $Li_{x/3}Ti_{2/3}O_2$; transition-metal sulfides such as TiS_2 ; metals capable of forming an alloy with alkali metals such as Al, Pb, Sn, Bi and Si; cubic intermetallic compounds capable of intercalating alkali metals therewith, such as $AlSb$, Mg_2Si and $NiSi_2$; and lithium-containing nitrides such as $Li_{1-x}M_xN$, where M is a transition metal. They may be used singly or as a mixture of two or more of them. Among them, carbon materials capable of absorbing and desorbing alkali metal ions are most commonly used.

[0040] Examples of the conductive agent in the negative electrode include: natural graphites such as flake graphite; artificial graphites; carbon blacks such as acetylene black, ketchen black, channel black, furnace black, lamp black and thermal black; conductive fibers such as carbon fibers and metal fibers; carbon fluoride; metal powders such as a copper powder and a nickel powder, organic conductive materials such as polyphenylene derivatives. They may be used singly or as a mixture of two or more of them. Among them, artificial graphites, acetylene black and carbon fibers are particularly preferred.

[0041] The amount of the conductive agent used in the negative electrode mixture is preferably 1 to 50 parts by weight, and more preferably 1 to 30 parts by weight per 100 parts by weight of the negative electrode active material. Here, it is not necessary to use the conductive agent when the negative electrode active material has an electronic conductivity.

[0042] Examples of the binder in the negative electrode include polyethylene, polypropylene, polytetrafluoroethylene, polyvinylidene fluoride, styrene butadiene rubber, tetrafluoroethylene-hexafluoropropylene copolymers, tetrafluoroethylene-perfluoroalkyl vinyl ether copolymers, vinylidene fluoride-hexafluoropropylene copolymers, vinylidene fluoride-chlorotrifluoroethylene copolymers, ethylene-tetrafluoroethylene copolymers, polychlorotrifluoroethylene, vinylidene

fluoride-pentafluoropropylene copolymers, propylene-tetrafluoroethylene copolymers, ethylene-chlorotrifluoroethylene copolymers, vinylidene fluoride-hexafluoropropylene-tetrafluoroethylene copolymers, vinylidene fluoride-perfluoromethyl vinyl ether-tetrafluoroethylene copolymers, ethylene-acrylic acid copolymers, ethylene-methacrylic acid copolymers, ethylene-methyl acrylate copolymers and ethylene-methyl methacrylate copolymers. They may be used singly or as a mixture of two or more of them. Among them, styrene butadiene rubber, polyvinylidene fluoride, ethylene-acrylic acid copolymers, ethylene-methacrylic acid copolymers, ethylene-methyl acrylate copolymers, ethylene-methyl methacrylate copolymers are particularly preferred.

[0043] As the current collector in the negative electrode, for example, one made of a stainless steel, nickel, copper, a copper alloy, titanium, carbon or a conductive polymer is used. Among them, a current collector made of copper or a copper alloy is particularly preferred. The surface of the current collector may be coated with carbon, nickel, titanium or the like, or it may also be oxidized. It is preferred to form asperities on the surface of the current collector. The current collector may be in the form of a foil, film, sheet, net, punched sheet, lath sheet, porous sheet, foamed sheet, nonwoven fabric or the like. Generally, the thickness of the current collector in the negative electrode is 1 to 500 μm .

(ii) Positive electrode

[0044] The positive electrode is fabricated, for example, by applying onto the surface of a current collector, a positive electrode mixture containing a positive electrode active material, a conductive agent, a binder and the like.

[0045] Examples of the positive electrode active material include Li_2CoO_2 , Li_2NiO_2 , Li_2MnO_2 , $\text{Li}_2\text{Co}_2\text{Ni}_{1-x}\text{O}_2$, $\text{Li}_2\text{Co}_2\text{M}_{1-x}\text{O}_2$, $\text{Li}_2\text{Ni}_{1-x}\text{M}_x\text{O}_2$, $\text{Li}_2\text{Mn}_{2-x}\text{M}_x\text{O}_4$, $\text{Li}_2\text{Mn}_{2-x}\text{M}_x\text{O}_4$, where M is at least one element selected from the group consisting of Na, Mg, Sc, Y, Mn, Fe, Co, Ni, Cu, Zn, Al, Cr, Pb, Sb and B, and x, y and z satisfy $0 \leq x \leq 1.2$, $0 \leq y \leq 0.9$, and $2.0 \leq z \leq 2.3$. The above value of x increases or decreases during the charging and discharging of the battery. Additionally, transition metal chalcogenides, lithium-containing vanadium oxides, lithium-containing niobium oxides, conductive conjugated polymers, Chevrel phase compounds or the like may also be used as the positive electrode active material. They may be used singly or as a mixture of two or more of them. The average particle size of the negative electrode active material is preferably 1 to 30 μm .

[0046] Examples of the conductive agent in the positive electrode include: natural graphites such as flake graphite; artificial graphites; carbon blacks such as acetylene black, ketchen black, channel black, furnace black, lamp black and thermal black; conductive fibers such as carbon fibers and metal fibers; carbon fluoride; metal powders such as a copper, nickel, aluminum or silver powder; conductive whiskers such as zinc oxide and potassium titanate; conductive metal oxides such as titanium oxide; organic conductive materials such as polyphenylene derivatives. They may be used singly or as a mixture of two or more of them. Among them, artificial graphites, acetylene black and a nickel powder are particularly preferred. The amount of the conductive agent used in the positive electrode mixture is preferably 1 to 50 parts by weight, more preferably 1 to 30 parts by weight, and in the case that a carbon black or a graphite is used, further preferably 2 to 15 parts by weight per 100 parts by weight of the positive electrode active material.

[0047] Examples of the binder in the positive electrode include polyethylene, polypropylene, polytetrafluoroethylene, polyvinylidene fluoride, tetrafluoroethylene-hexafluoroethylene copolymers, tetrafluoroethylene-hexafluoropropylene copolymers, tetrafluoroethylene-perfluoroalkyl vinyl ether copolymers, vinylidene fluoride-hexafluoropropylene copolymers, vinylidene fluoride-chlorotrifluoroethylene copolymers, ethylene-tetrafluoroethylene copolymers, polychlorotrifluoroethylene, vinylidene fluoride-pentafluoropropylene copolymers, propylene-tetrafluoroethylene copolymers, ethylene-chlorotrifluoroethylene copolymers, vinylidene fluoride-hexafluoropropylene-tetrafluoroethylene copolymers, vinylidene fluoride-perfluoromethyl vinyl ether-tetrafluoroethylene copolymers, ethylene-acrylic acid copolymers, ethylene-methacrylic acid copolymers, ethylene-methyl acrylate copolymers and ethylene-methyl methacrylate copolymers. Among them, polyvinylidene fluoride and polytetrafluoroethylene are particularly preferred.

[0048] As the current collector in the positive electrode, for example, one made of a stainless steel, aluminum, an aluminum alloy, titanium, carbon or a conductive polymer may be used. Among them, a current collector made of aluminum or an aluminum alloy is preferred. The surface of current collector may be coated with carbon, titanium or the like, or it may also be oxidized. It is preferred to form asperities on the surface of the current collector. The current collector may be in the form of a foil, film, sheet, net, punched sheet, lath sheet, porous sheet, foamed sheet and nonwoven fabric. Generally, the thickness of the current collector in the positive electrode is 1 to 500 μm .

[0049] The positive electrode mixture or the negative electrode mixture may contain various additives, in addition to the above-described materials. They may also contain a gel comprising a polymer material retaining a non-aqueous electrolyte.

(iii) Separator

[0050] As the separator, an insulating microporous thin film having a high ionic permeability and a predetermined mechanical strength may be used. Additionally, it is preferred to give the separator the capability to increase the re-

(ii) Non-aqueous solvent

[0060] Preferred examples of the non-aqueous solvent include polar protic organic solvents and polar aprotic organic solvents. They may be used singly or as a mixture of two or more of them.

[0061] Examples of the polar protic organic solvent include: monohydric alcohols such as ethanol, propanol, butanol, pentanol, hexanol, cyclobutanol, cyclopentanol and benzyl alcohol; polyhydric alcohols such as ethylene glycol, propylene glycol, glycerin, methyl cellosolve, ethyl cellosolve, methoxypropylene glycol and dimethoxypropanol; oxalalcohol compounds; and the like. They may be used singly or as a mixture of two or more of them.

[0062] Examples of the polar aprotic organic solvent include: amide compounds such as N-methylformamide, N,N-dimethylformamide, N-ethylformamide and N,N-diethylformamide; cyclic carboxylic acid esters such as γ -butyrolactone and γ -valerolactone; cyclic carbonic acid esters such as ethylene carbonate, propylene carbonate, butylene carbonate and vinylene carbonate; other solvents such as dimethylsulfoxide, 1,3-dioxolane, formamide, acetamide, dimethylformamide, dioxolane, acetonitrile, propynitrile, nitromethane, ethyl monoglyme, phosphoric acid triesters, trimethoxymethane, dioxolane derivatives, sulfolane, methylsulfolane, 1,3-dimethyl-2-imidazolidinone, 3-methyl-2-oxazolidinone, ethyl ether, 1,3-propanesultone, anisole and N-methylpyrrolidone; and the like. They may be used singly or as a mixture of two or more of them.

[0063] Although the amount of the solute used is not particularly limited, it is preferably 0.1 to 40 parts by weight per 100 parts by weight of the non-aqueous solvent.

[0064] The voltage proof of the capacitor can be improved by adding boric acid, a complex compound of boric acid and a polysaccharide (e.g., mannitol or sorbitol), a complex compound of boric acid and a polyhydric alcohol (e.g., ethylene glycol or glycerin), a surfactant, colloidal silica or the like in the non-aqueous electrolyte.

[0065] Further, an aromatic nitro compound such as p-nitrobenzoic acid or p-nitrophenol; a phosphorus compound such as phosphoric acid, phosphorous acid, polyphosphoric acid or an acidic phosphoric acid ester compound; an oxycarboxylic acid compound or the like may be added to the electrolyte in order to reduce current leakage and to make a hydrogen gas absorbed thereby.

Embodiment 4

[0066] In this embodiment, descriptions will be made on an electrolytic capacitor comprising the non-aqueous electrolyte of Embodiment 3. The electrolytic capacitor comprises a positive electrode foil having a dielectric layer; a negative electrode foil; a separator interposed between the positive electrode foil and the negative electrode foil; and the above non-aqueous electrolyte.

[0067] The electrolytic capacitor comprises an element obtained by rolling up a positive electrode foil and a negative electrode foil with a separator interposed therebetween; a non-aqueous electrolyte with which the capacitor element is impregnated; and a case for accommodating them. The opening of the case is sealed with a sealing member.

[0068] As the positive electrode foil, for example, an aluminum foil is used. A dielectric layer can be formed on the positive electrode foil, for example, by etching the positive electrode foil to expand the surface area thereof in a boric acid and applying a positive potential of 300 to 600 V to the positive electrode foil versus the counter electrolyte. Through such a step, an oxide film used as the dielectric layer is formed on the positive electrode foil.

[0069] As the negative electrode foil, for example, an aluminum foil is used.

[0070] As the separator, for example, a nonwoven or woven fabric made of a kraft pulp fiber is used.

[0071] Hereinbelow, the present invention will be specifically described with reference to examples, but it should be understood that the invention is not construed as being limited thereto.

EXAMPLE 1

[0072] Each of solutes listed in Table 1 was dissolved at a concentration of 1.0 mol/liter in a mixed solvent containing ethylene carbonate and ethylmethyl carbonate at a volume ratio of 1:3 thereby to prepare each of electrolytes A to R. Table 1 shows the ionic conductivities at 20 °C of the respective electrolytes measured by using a bridge-type conductivity meter. Here, the ionic conductivities of electrolytes Q and R containing LiBF_4 and LiPF_6 , respectively, at a concentration of 1.0 mol/liter, were also measured for comparison.

[Table 1]

Electrolyte	Solute	Ionic conductivity (mS/cm)
A	$\text{LiB}(\text{CF}_3)_4$	7.52
B	$\text{LiBF}(\text{CF}_3)_3$	5.11

[Table 1] (continued)

Electrolyte	Solute	Ionic conductivity (mS/cm)
C	$\text{LiBF}_2(\text{CF}_3)_2$	4.02
D	$\text{LiBF}_3(\text{CF}_3)$	3.21
E	$\text{LiB}(\text{C}_2\text{F}_5)_4$	8.63
F	$\text{LiBF}(\text{C}_2\text{F}_5)_3$	6.89
G	$\text{LiBF}_2(\text{C}_2\text{F}_5)_2$	4.62
H	$\text{LiBF}_3(\text{C}_2\text{F}_5)$	3.31
I	$\text{LiB}(\text{CF}_3\text{SO}_2)_4$	8.55
J	$\text{LiBF}(\text{CF}_3\text{SO}_2)_3$	7.62
K	$\text{LiBF}_2(\text{CF}_3\text{SO}_2)_2$	5.83
L	$\text{LiBF}_3(\text{CF}_3\text{SO}_2)$	4.47
M	$\text{LiB}(\text{C}_2\text{F}_5\text{SO}_2)_4$	8.21
N	$\text{LiBF}(\text{C}_2\text{F}_5\text{SO}_2)_3$	7.18
O	$\text{LiBF}_2(\text{C}_2\text{F}_5\text{SO}_2)_2$	5.23
P	$\text{LiBF}_3(\text{C}_2\text{F}_5\text{SO}_2)$	3.98
Q	LiBF_4	2.91
R	LiPF_6	8.52

[0073] From the results shown in Table 1, it can be seen that the use of a solute having one or more perfluoroalkyl group or perfluoroalkylsulfonic acid group gives a higher ionic conductivity to the non-aqueous electrolyte than the use of LiBF_4 .

EXAMPLE 2

[0074] The potential window of each solute was measured by using the electrolytes A to R prepared in Example 1.

[0075] Test cells were assembled by using reference electrodes, counter electrodes, test electrodes and the electrolytes A to R. Here, a lithium foil was used for the reference electrode and the counter electrode, and a platinum plate having a surface area of 1 cm^2 was used for the test electrode.

[0076] Subsequently, the potential of each test electrode was scanned at 10 mV/sec to the oxidation direction. The potential of the test electrode versus the potential of the reference electrode when a current of $100 \text{ } \mu\text{A/cm}^2$ was passed was regarded as an oxidation decomposition potential. Meanwhile, the potential of each test electrode was scanned at 10 mV/sec to the reduction direction. The potential of the test electrode versus the potential of the reference electrode when a current of $100 \text{ } \mu\text{A/cm}^2$ was passed was regarded as a reduction decomposition potential. The results are shown in Table 2.

[Table 2]

Electrolyte	Solute	Reduction decomposition potential (V)	Oxidation decomposition potential (V)
A	$\text{LiB}(\text{CF}_3)_4$	<0.00	6.48
B	$\text{LiBF}(\text{CF}_3)_3$	<0.00	6.01
C	$\text{LiBF}_2(\text{CF}_3)_2$	<0.00	5.83
D	$\text{LiBF}_3(\text{CF}_3)$	<0.00	5.67
E	$\text{LiB}(\text{C}_2\text{F}_5)_4$	<0.00	6.32
F	$\text{LiBF}(\text{C}_2\text{F}_5)_3$	<0.00	6.11
G	$\text{LiBF}_2(\text{C}_2\text{F}_5)_2$	<0.00	5.94

[Table 2] (continued)

	Electrolyte	Solute	Reduction decomposition potential (V)	Oxidation decomposition potential (V)
5	H	$\text{LiBF}_3(\text{C}_2\text{F}_5)_3$	<0.00	5.71
	I	$\text{LiB}(\text{CF}_3\text{SO}_2)_4$	<0.00	5.96
	J	$\text{LiBF}(\text{CF}_3\text{SO}_2)_3$	<0.00	5.89
10	K	$\text{LiBF}_2(\text{CF}_3\text{SO}_2)_2$	<0.00	5.66
	L	$\text{LiBF}_3(\text{CF}_3\text{SO}_2)$	<0.00	5.37
	M	$\text{LiB}(\text{C}_2\text{F}_5\text{SO}_2)_4$	<0.00	6.10
	N	$\text{LiBF}(\text{C}_2\text{F}_5\text{SO}_2)_3$	<0.00	5.98
15	O	$\text{LiBF}_2(\text{C}_2\text{F}_5\text{SO}_2)_2$	<0.00	5.73
	P	$\text{LiBF}_3(\text{C}_2\text{F}_5\text{SO}_2)$	<0.00	5.49
	Q	LiBF_4	<0.00	6.04
20	R	LiPF_6	<0.00	6.45

[0077] In Table 2, the potential window of each solute having one or more perfluoroalkyl group or perfluoroalkylsulfonic acid group is substantially equal to or wider than that of LiBF_4 . This demonstrates that these solutes are suitable for a non-aqueous electrolyte battery such as a lithium battery.

EXAMPLE 3

[0078] Cylindrical lithium batteries A to R were fabricated by using the electrolytes A to R prepared in Example 1, respectively. FIG. 1 shows a vertical sectional view of the battery thus produced.

[0079] A positive electrode slurry was applied onto a positive electrode current collector made of an aluminum foil, which was then dried and rolled thereby to produce a positive electrode plate 1. The positive electrode slurry was prepared by dispersing in dehydrated N-methylpyrrolidinone, a mixture of 85 parts by weight of a lithium cobaltate powder, 10 parts by weight of a carbon powder as a conductive agent and 5 parts by weight of polyvinylidene fluoride as a binder.

[0080] A negative electrode slurry was applied onto a negative electrode current collector made of a copper foil, which was then dried and rolled thereby to produce a negative electrode plate 2. The negative electrode slurry was prepared by dispersing in dehydrated N-methylpyrrolidinone, a mixture of 75 parts by weight of an artificial graphite powder, 20 parts by weight of a carbon powder as a conductive agent and 5 parts by weight of polyvinylidene fluoride as a binder.

[0081] The positive electrode plate 1 and the negative electrode plate 2 were rolled up together, with a separator 3 made of polyethylene interposed therebetween, thereby to obtain an electrode assembly. Insulating rings 6 and 7 were provided on the top and bottom portions of the electrode assembly, respectively. The electrode assembly thus obtained was accommodated in a battery case 8 made of a stainless steel. Then, a positive electrode lead 4 made of aluminum, which was attached to the positive electrode plate 1, was connected to a positive electrode terminal 10 disposed on a sealing plate 9. A negative electrode lead 5 made of nickel, which was attached to the negative electrode plate 2, was connected to the bottom of the battery case 8. After a predetermined electrolyte was injected into the battery case 8, the opening of the battery case 8 was sealed with the sealing plate 9 thereby to obtain a battery.

[0082] Each battery thus obtained was 18 mm in diameter and 65 mm in height with a nominal capacity of 1800 mAh. This battery was charged at a constant voltage of 4.2 V, and then discharged at a current of 360 mA or 3600 mA. The discharge capacities thus obtained are shown in Table 3.

[0083] After being discharged at a current of 360 mA, each battery was charged again at a constant voltage of 4.2 V. The charged battery was stored at 60 °C for one month, and was discharged at a current of 3600 mA thereafter. The discharge capacities thus obtained are also shown in Table 3.

[Table 3]

Battery	Electrolyte	Discharge capacity at 360 mA (mAh)	Discharge capacity at 3600 mA (mAh)	Discharge capacity at 3600 mA after storage (mAh)
A	A	1407	1052	875
B	B	1318	960	851
C	C	1297	920	805
D	D	1223	866	749
E	E	1638	1263	1127
F	F	1417	1002	888
G	G	1345	953	841
H	H	1240	885	766
I	I	1622	1238	1217
J	J	1582	1194	1041
K	K	1354	997	876
L	L	1305	927	812
M	M	1518	1179	1003
N	N	1429	1058	912
O	O	1332	978	857
P	P	1285	904	789
Q	Q	1105	843	432
R	R	1595	1210	1090

[0084] From the result shown in Table 3, it can be seen that the present invention provides a highly reliable lithium battery which exhibits excellent high-rate discharge characteristics as well as high temperature storage characteristics.

EXAMPLE 4

[0085] Non-aqueous electrolytes 1 to 27 were prepared by dissolving solutes listed in Table 4 at a concentration of 1.0 mol/liter in a mixed solvent containing ethylene carbonate and ethylmethyl carbonate at a volume ratio of 1:3. Table 4 shows the ionic conductivities of the respective electrolytes at 20 °C measured by using the bridge-type conductivity meter. Here, the ionic conductivities of electrolytes 25 to 27 containing $(CH_3)_4NBF_4$, $(C_2H_5)_4NBF_4$ and $(CH_3)_3C)_4NBF_4$, respectively, at a concentration of 1.0 mol/liter, were also measured for comparison.

[Table 4]

Electrolyte	Solute	Ionic conductivity (mS/cm)
1	$(CH_3)_4NB(CF_3)_4$	7.22
2	$(CH_3)_4NBF(CF_3)_3$	5.02
3	$(CH_3)_4NBF_2(CF_3)_2$	3.98
4	$(CH_3)_4NBF_3(CF_3)$	3.09
5	$(CH_3)_4NB(C_2F_5)_4$	8.31
6	$(CH_3)_4NBF(C_2F_5)_3$	6.72
7	$(CH_3)_4NBF_2(C_2F_5)_2$	4.43
8	$(CH_3)_4NBF_3(C_2F_5)$	3.27
9	$(C_2H_5)_4NB(CF_3)_4$	6.88

[Table 4] (continued)

Electrolyte	Solute	Ionic conductivity (mS/cm)
10	$(C_2H_5)_4NBF(CF_3)_3$	4.71
11	$(C_2H_5)_4NBF_2(CF_3)_2$	3.60
12	$(C_2H_5)_4NBF_3(CF_3)$	2.98
13	$(C_2H_5)_4NB(C_2F_5)_4$	7.19
14	$(C_2H_5)_4NBF(C_2F_5)_3$	4.97
15	$(C_2H_5)_4NBF_2(C_2F_5)_2$	3.89
16	$(C_2H_5)_4NBF_3(C_2F_5)$	3.01
17	$((CH_3)_2C)_4NB(CF_3)_4$	6.19
18	$((CH_3)_2C)_4NBF(CF_3)_3$	4.45
19	$((CH_3)_2C)_4NBF_2(CF_3)_2$	3.32
20	$((CH_3)_2C)_4NBF_3(CF_3)$	2.69
21	$((CH_3)_2C)_4NB(C_2F_5)_4$	6.74
22	$((CH_3)_2C)_4NBF(C_2F_5)_3$	4.38
23	$((CH_3)_2C)_4NBF_2(C_2F_5)_2$	3.26
24	$((CH_3)_2C)_4NBF_3(C_2F_5)$	2.72
25	$(CH_3)_4NBF_4$	2.79
26	$(C_2H_5)_4NBF_4$	2.36
27	$((CH_3)_3C)_4NBF_4$	2.05

[0086] From the results shown in Table 4, it can be seen that the use of each solute having one or more perfluoroalkyl group gives a higher ionic conductivity to the non-aqueous electrolyte than the use of the solute whose anion portion is BF_4 .

EXAMPLE 5

[0087] The potential window of each solute was measured in the same manner as in Example 2, except for using the non-aqueous electrolytes 1 to 27 prepared in Example 4. The results are shown in Table 5.

[Table 5]

Electrolyte	Solute	Reduction decomposition potential (V)	Oxidation decomposition potential (V)
1	$(CH_3)_4NB(CF_3)_4$	<0.00	6.47
2	$(CH_3)_4NBF(CF_3)_3$	<0.00	6.16
3	$(CH_3)_4NBF_2(CF_3)_2$	<0.00	6.04

24	$((CH_3)_3C)_4NBF_3(C_2F_5)$	<0.00	5.81
25	$(CH_3)_4NBF_4$	<0.00	6.02
26	$(C_2H_5)_4NBF_4$	<0.00	5.93
27	$((CH_3)_3C)_4NBF_4$	<0.00	5.82

[0088] In Table 5, the potential window of each solute having one or more perfluoroalkyl group is substantially equal to or wider than that of each solute whose anion portion is BF_4 . This demonstrates that these solutes are suitable for electrolytic capacitors.

EXAMPLE 6

[0089] Electrolytic capacitors comprising the electrolytes 1 to 27 prepared in Example 4 were produced in the following manner.

[0090] The surface of an aluminum foil having a thickness of 100 μm was etched by electrolysis. A positive potential of 500 V versus the potential of the counter electrode was applied on the etched aluminum foil in a boric acid, which was then stood still for 15 minutes. As a result, an aluminum oxide film used as a dielectric layer was formed on the surface of the aluminum foil.

[0091] Subsequently, an aluminum foil having an aluminum oxide film used as a positive electrode foil and another aluminum foil used as a negative electrode foil were rolled up together, with a separator made of a kraft pulp fiber interposed therebetween, thereby to obtain a capacitor element. The capacitor element thus obtained was impregnated with a predetermined non-aqueous electrolyte. The capacitor element impregnated with the non-aqueous electrolyte was accommodated in a case made of aluminum. Then, the opening of the case was sealed with an insulating sealing member, and the leads of the positive electrode foil and the negative electrode foil were threaded through the sealing member to be pulled outside, thereby obtaining an electrolytic capacitor.

[0092] Subsequently, the electrolytic capacitor thus obtained was evaluated for the frequency characteristics.

[0093] A circuit as shown in FIG. 2 was assembled, which comprised a direct-current power source 11, an electrolytic capacitor 12, a resistor 13, a relay switch 14 and a voltmeter 15. The negative side of the direct-current power source, the negative electrode foil side of the electrolytic capacitor and the resistor were grounded. Then, the relay switch was activated at a duty ratio of 0.5 (50%) and at a frequency of 60 Hz to apply a pulse voltage on the electrolytic capacitor. Here, the upper limit of the applied voltage was set at 3.0 V. FIG. 3 shows the change in the difference between the potentials of the negative electrode foil and the positive electrode foil of the electrolytic capacitor.

[0094] The voltage value of the electrolytic capacitor was recorded 1/240 second after the start of the charging during each charging interval, and this measurement was conducted for 10 seconds. The average values of the recorded

voltages are shown in Table 6. It can be said that the charge/discharge characteristics improve with an increase in the speed of the potential rise on the positive electrode foil.

[Table 6]

Capacitor	Electrolyte	Solute	Voltage (V)
1	1	$(\text{CH}_3)_4\text{NB}(\text{CF}_3)_4$	2.94
2	2	$(\text{CH}_3)_4\text{NBF}(\text{CF}_3)_3$	2.80
3	3	$(\text{CH}_3)_4\text{NBF}_2(\text{CF}_3)_2$	2.59
4	4	$(\text{CH}_3)_4\text{NBF}_3(\text{CF}_3)$	2.28
5	5	$(\text{CH}_3)_4\text{NB}(\text{C}_2\text{F}_5)_4$	2.96
6	6	$(\text{CH}_3)_4\text{NB}(\text{C}_2\text{F}_5)_3$	2.89
7	7	$(\text{CH}_3)_4\text{NBF}_2(\text{C}_2\text{F}_5)_2$	2.66
8	8	$(\text{CH}_3)_4\text{NBF}_3(\text{C}_2\text{F}_5)$	2.35
9	9	$(\text{C}_2\text{H}_5)_4\text{NB}(\text{CF}_3)_4$	2.51
10	10	$(\text{C}_2\text{H}_5)_4\text{NBF}(\text{CF}_3)_3$	2.74
11	11	$(\text{C}_2\text{H}_5)_4\text{NBF}_2(\text{CF}_3)_2$	2.44
12	12	$(\text{C}_2\text{H}_5)_4\text{NBF}_3(\text{CF}_3)$	2.20
13	13	$(\text{C}_2\text{H}_5)_4\text{NB}(\text{C}_2\text{F}_5)_4$	2.93
14	14	$(\text{C}_2\text{H}_5)_4\text{NB}(\text{C}_2\text{F}_5)_3$	2.78
15	15	$(\text{C}_2\text{H}_5)_4\text{NBF}_2(\text{C}_2\text{F}_5)_2$	2.53
16	16	$(\text{C}_2\text{H}_5)_4\text{NBF}_3(\text{C}_2\text{F}_5)$	2.22
17	17	$((\text{CH}_3)_3\text{C})_4\text{NB}(\text{CF}_3)_4$	2.88
18	18	$((\text{CH}_3)_3\text{C})_4\text{NBF}(\text{CF}_3)_3$	2.69
19	19	$((\text{CH}_3)_3\text{C})_4\text{NBF}_2(\text{CF}_3)_2$	2.39
20	20	$((\text{CH}_3)_3\text{C})_4\text{NBF}_3(\text{CF}_3)$	2.15
21	21	$((\text{CH}_3)_3\text{C})_4\text{NB}(\text{C}_2\text{F}_5)_4$	2.90
22	22	$((\text{CH}_3)_3\text{C})_4\text{NB}(\text{C}_2\text{F}_5)_3$	2.63
23	23	$((\text{CH}_3)_3\text{C})_4\text{NBF}_2(\text{C}_2\text{F}_5)_2$	2.33
24	24	$((\text{CH}_3)_3\text{C})_4\text{NBF}_3(\text{C}_2\text{F}_5)$	2.16
25	25	$(\text{CH}_3)_4\text{NBF}_4$	2.18
26	26	$(\text{C}_2\text{H}_5)_4\text{NBF}_4$	2.11
27	27	$((\text{CH}_3)_3\text{C})_4\text{NBF}_4$	2.02

[0095] From the results shown in Table 6, it can be seen that the electrolytic capacitor using each solute having one or more perfluoroalkyl group exhibits superior frequency characteristics. This is presumably due to the increase in the ionic conductivity of the non-aqueous electrolyte.

[0096] When a similar measurement was conducted at an increased charge voltage, the electrolytic capacitor using each solute having one or more perfluoroalkyl group showed little deterioration in the charge/discharge characteristics. The deterioration of the charge/discharge characteristics was presumably due to the decomposition of an anion by oxidation.

[0097] From the results, it can be seen that the use of each solute having one or more perfluoroalkyl group can improve the stability of an electrolytic capacitor.

[0098] As described above, the present invention uses a solute which has a thermal stability substantially equal to that of LiBF_4 and an anion portion having a high electronegativity, and easily dissociates into ions. Therefore, it provides a non-aqueous electrolyte having a high thermal stability as well as a high ionic conductivity. Furthermore, the use of

8. An electrolytic capacitor, comprising a positive electrode foil having a dielectric layer; a negative electrode foil; a separator interposed between said positive electrode foil and said negative electrode foil; and the non-aqueous electrolyte in accordance with claim 5.

5 9. An electric double layer capacitor, comprising a pair of polarizable electrodes made of activated carbon; a separator interposed between said electrodes; and the non-aqueous electrolyte in accordance with claim 5.
